OF AMOUNT OF SUBSTANCE**

**A WORKSHOP FOR EURACHEM COMMITTEE MEMBERS  
AND INVITEES**

**11 AND 12 NOVEMBER 1992**

Organised at the request of  
**EURACHEM**  
A focus for analytical chemistry in Europe

©1992: P De Bièvre

**Some replies to the request submitted  
by the organizers:**

**“right decisions”  
based on measurement results in chemistry  
require a “correct basis” for  
measurement results**

**a “correct basis” for measurement results requires  
“correct understanding” of  
measurement results as well as of all essential  
concepts related to the measurement concerned**

**“correct understanding” of  
measurement results in chemistry  
requires *clearly defined concepts* in measurement  
[i.e. it requires the elimination of CBUs  
Conceptual Barriers to Understanding]**

the 2008 International Vocabulary of Metrology -  
Basic and General Concepts and associated terms  
(VIM) edition 3  
Guide JCGM 200:2008  
[ISO/IEC Guide 99:2007]  
[www.bipm.org/en/publications/guides/vim.html](http://www.bipm.org/en/publications/guides/vim.html)

the 2010 IUPAC Recommendations on  
“Metrological Traceability of Measurement Results in  
Chemistry

consistent translation of a term from one language into other languages used on the **intercontinental** scene is only possible under a basic condition:

one must  
**understand the concept behind the term**  
before  
**being able to translate the term**  
**= justification for VIM 2008**

**One never gets the "truth" when measuring (it requires a 'reference' to call something "true")**

**but we can make a "model" of our best knowledge of what we think is "close to the truth" :**

**it is a quantity equation  $Y = f(X_1, X_2, X_3, \dots)$  called 'measurement function' (VIM3, entry 2.49) ;**

**simple example:  $n = l \cdot t$**

**it relates an output quantity  $Y$  (the 'measurand') we intend to measure (2008 VIM definition), to one or more input quantities  $X_i$  which are subject to measurement (1993 definition of 'measurand')**

The 19<sup>th</sup> / 20<sup>th</sup> century concepts  
'true value' and 'error' are being abandoned  
in the period  $2\ 000 \pm 10$

in favour of

- the 'metrological traceability' of these results,  
and
- their 'measurement uncertainty'

'Metrological traceability' reveals us where the  
measurement result comes from  
by revealing the "trace" along which it comes  
to us

**the times that we could "declare" a  
measurement result as a number times a unit  
without further explanation, are over**

- A measurement result now contains by  
definition the associated measurement  
uncertainty as a "measure of doubt" about  
that result
- **the times that we could "declare" a  
measurement result without a measurement  
uncertainty, are over**

**Metrological traceability is *decided* by the analyst  
before the measurement**

**that logically puts the analyst (back) in full  
charge -and responsibility-  
of the measured quantity value  
(not the statistician)**

**metrological traceability is a *prerequisite* to  
measurement uncertainty  
hence, measurement uncertainty is dependent  
on a variety of *decisions***

**measurement uncertainty is *evaluated* by the  
analyst *after* the measurement  
(evaluation includes *decisions* because  
choices are involved)**

**it logically puts the analyst (back) in full charge  
-and responsibility- of the  
measurement uncertainty  
(not the statistician)  
because *decisions* must be made**

## There is news !

- **The good news:**

there is now a new  
International Vocabulary of Metrology (“VIM”)  
which covers chemical measurement  
(that was not the case in 1984 (“VIM1”) and 1993 (“VIM2”))

- **The bad news:**

everybody will have to go back to the workbench and study

- **But ... the VIM is extremely helpful by  
clarifying and simplifying our thinking and  
our language**

## The revision of “VIM2” (yielding “VIM3”)

1. VIM2 (1993) was written for physics and engineering  
by physicists and engineers

2. For the first time in history, chemical measurement is  
covered by VIM3

3. Important change of title:

*from*

“International Vocabulary of basic and general Terms  
in Metrology” (VIM2)

*to*

“International Vocabulary of Metrology - basic and  
general Concepts and associated Terms – VIM  
(VIM3)

### The revision of VIM2 (yielding VIM3):

4. uses the "substitution principle":  
any concept used in the definition of another concept must be replaceable by the definition of that concept given elsewhere in VIM3 (to make that clear, it is printed in bold)
5. uses GUM, even if the definition of some GUM concepts are already up for refinement in "GUM2" (which may be planned)

### The three "c" s

- the decision to acquire new knowledge **curiosity**
- the decision to exploit the fruit of curiosity **commerce**
- the decision to regulate the commerce **control**

with sincere wishes  
to all  
for  
good discussions!

## 2.2 metrology

- science of **measurement** and its application
- Note Metrology includes all theoretical and practical aspects of measurement, whatever the **measurement uncertainty** and field of application.

## 2.3 measurand

### 2.3 measurand

**quantity** intended to be measured

- the English “quantity” is not the translation (anymore) from the French “quantite”
- “quantity” in English has become the translation of the French “grandeur de mesure”
- “amount” has become the translation of the French “quantite”
- the French “quantite” has now to be translated into the English “amount”

**realizing an ‘intention’ implies taking a *decision***

introduces the *intention* of the analyst  
 (“*intended to be measured*”)

similarly,

“fitness for *intended use*”  
is henceforth used rather than  
“fitness for purpose”

**the choice of the measurand is a  
*decision***

## 1.1 quantity

property of a phenomenon, body or substance,  
where the property has a magnitude that can be  
expressed as a number and a reference.

Examples : see VIM3

- Note 2 A reference can be a **measurement unit**, a **measurement procedure**, a **reference material**, or a combination of such

*a decision*

### Warning:

don't confuse quantity and carrier of quantity

quantity	carrier
mass, diameter, height, density	metal cilinder, tree
velocity, wavelength, frequency, colour	electromagnetic wavelength (in the range 400-800 nm)
amount-of-substance, mass, density, pH value	NaCl solution, water in a container

Ref: U Feller METAS

## 2.3 measurand

- quantity we measure:  
e.g, length, mass, temperature, volume, pressure, amount concentration, mass concentration, mass fraction, electric current, ...
- the specification of the measurand results from the intention of the analyst about what (s)he is going to measure
- **it is a *decision made before the measurement***
- the measurand can be operationally defined, e.g.,  
leachable Cd concentration in a ceramic plate, measured according to a specified procedure

## 2.9 measurement result

set of **quantity values** being attributed to a **measurand** together with any other available information

Note 2: A measurement result is generally expressed as a single **measured quantity value** and a **measurement uncertainty**

## 2.36 measurement uncertainty

non-negative parameter characterizing the dispersion of the **quantity values** being attributed to a **measurand**, based on the information used

## 2.28 Type A evaluation of measurement

**uncertainty** evaluation of a component of **measurement uncertainty** by a statistical analysis of **measured quantity values** obtained under defined measurement conditions

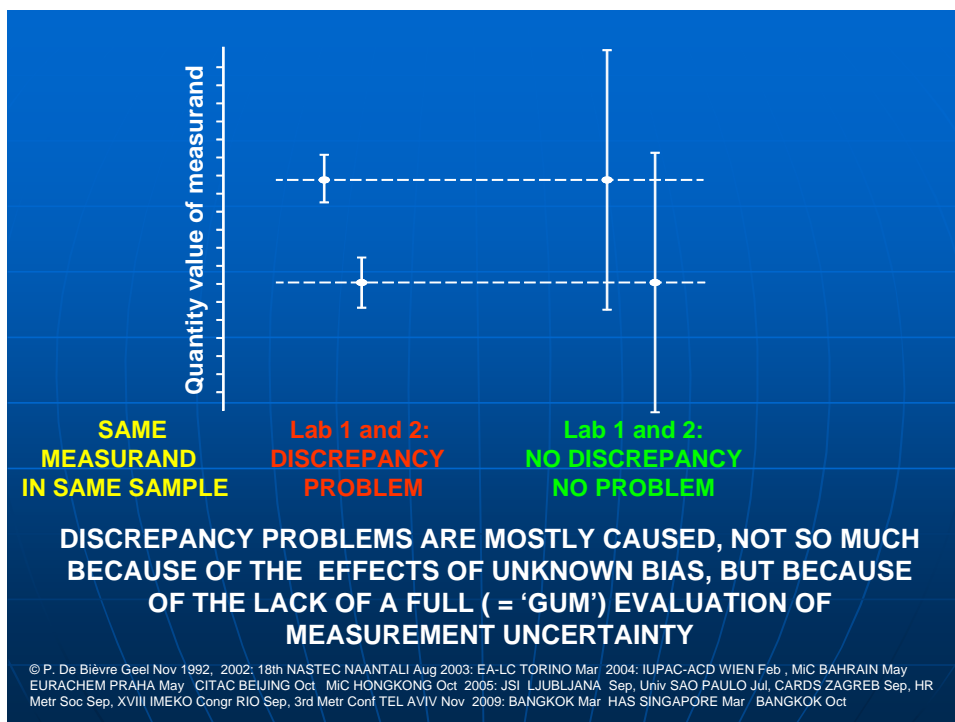

## 2.29 Type B evaluation of measurement uncertainty

evaluation of a component of **measurement uncertainty** determined by means other than a statistical analysis of **Type A evaluation of measurement uncertainty**

(sometimes the basis of Type B evaluation is called "subjective information" - GUM 3.3.5)

**Type B evaluation implies decisions by the analyst**

P De Bièvre 2009: MCH V SAO PAULO Nov 2010: CITAC TEL-AVIV Jan

### ON THE **AVERAGE** THE DUCK WAS DEAD

A hunter fired both barrels of a shotgun at a duck.  
The first hit two feet in front, the second hit two feet behind.

***On the average the duck was dead.***

In duck hunting one wants to keep trying until a **single shot** hits the mark.

Source: J Ruzicka 1980 (at the habilitaion of K Heydorn KØBENHAVN)

***It is cheaper to perform less measurements,  
fix a target measurement uncertainty, and  
then have sufficiently small measurement uncertainty every time,  
than making many measurements and use the average***

These very important definitions put the ultimate task  
-and responsibility- for the measurement result  
(back) to the analyst responsible; this is absolutely  
correct because his/her professional skill and judgement  
is essential:

GUM 3.4.8: “The evaluation of uncertainty is neither a  
routine task nor a purely mathematical one; it depends  
on detailed knowledge of the nature of the measurand  
and of the measurement”

GUM 4.3.2: “Type B evaluation of standard uncertainty  
... calls for insight based on experience and general  
knowledge, and is a skill to be learned with practice”

The “culture” of statistics in chemical measurement, especially in Type A evaluation:

“culturing” the description of results  
**a posteriori**

does only describe a result in terms of a distribution of a set of values  
**a posteriori**

P De Bièvre 2009: MCH V SAO PAULO Nov 2010: CITAC TEL-AVIV Jan

“Life can only be  
*understood BACKWARDS*  
but it must be  
*lived FORWARDS*”

S. Kierkegaard, Danish philosopher,  
1813 – 1855

generating quality can only be done by the  
**analyst making *decisions***  
**before the measurement**

this is a matter of logics, even chrono-logics

## 2.6 measurement procedure

detailed description of a **measurement** according to one or more **measurement principles** and to a given **measurement method**, based on a **measurement model** and including any calculation to obtain a **measurement result**

Note 2: A **measurement procedure** can include a statement concerning a **target measurement uncertainty**

A quantity value obtained by an operationally defined measurement procedure can be designated as a metrological 'reference'

*A designation implies decisions by the analyst*

## 2.7 reference measurement procedure

**measurement procedure** accepted as providing **measurement results** fit for their *intended use* in

- assessing **measurement trueness** of **measured quantity values** obtained from other measurement procedures for **quantities** of the same **kind**,
  - in **calibration**, or
  - in characterizing **reference materials**

## 2.8 primary reference measurement procedure

**reference measurement procedure** used to obtain a **measurement result** without relation to a **measurement standard** for a **quantity** of the same **kind**

Note 1: The Consultative Committee for Amount of Substance – Metrology in Chemistry (CCQM) uses the term "primary method of measurement" for this concept

this definition prevents to use “primary” for non-metrological reason such as:

- prestige
- politics
- commerce

this also applies to the (mis-) use of the concept ‘primary measurement standard’ (see further)

**measurement procedure**  
**“accepted” as a reference measurement procedure,**  
**requires an agreement, hence a *decision***

P De Bièvre 2009: MCH V SAO PAULO Nov 2010: CITAC TEL-AVIV Jan

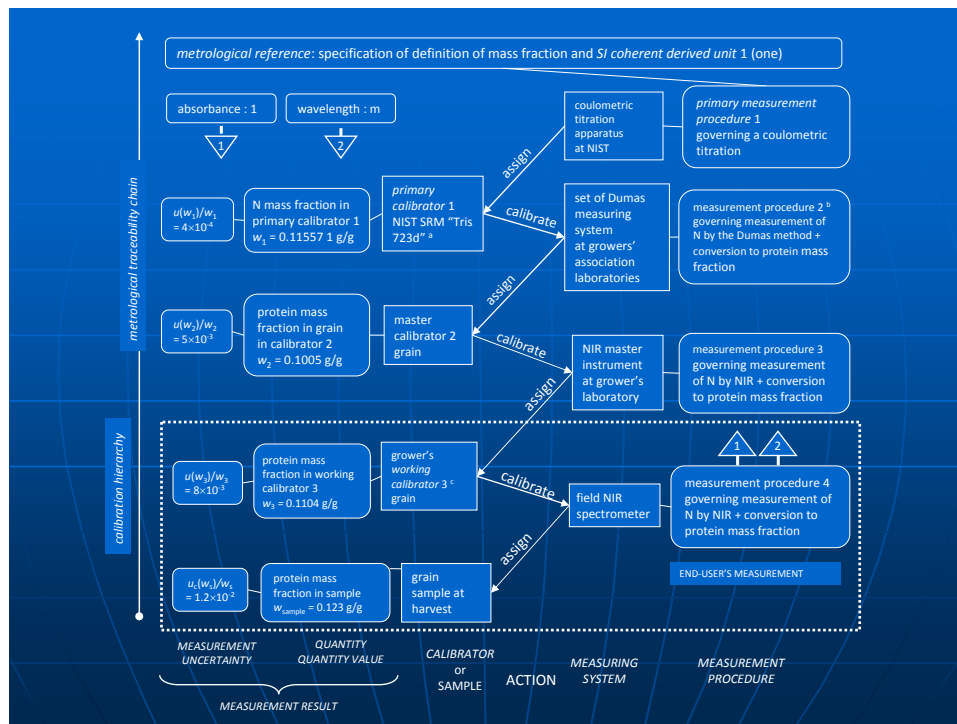

A measurement is almost never “absolute”;  
in extremely simplified terms, we could say that

it is a comparison of an unknown ‘quantity value’  
(embodied in a sample)  
to a known ‘quantity value’  
(embodied in a ‘measurement standard’):

the first link of a ‘metrological traceability chain’ is  
thereby born

we use the known ‘quantity value’ carried by  
(embodied in) the ‘measurement standard’  
(usually called ‘CRM’ in common parlance)  
to calibrate our ‘measuring system’  
hence a better term for this ‘measurement  
standard’ is ‘calibrator’

P De Bièvre 2009: MCH V SAO PAULO Nov 2010: CITAC TEL-AVIV Jan

- a measurement method has no fixed, i.e. constant, measurement uncertainty, but a specified reference measurement procedure has
  - a measurement procedure contains a detailed description depending on its *intended use* as a:
    - “reference measurement procedure”, or as a
    - “primary measurement procedure” (see further)
  - a measurement procedure enables to introduce the concept of “target measurement uncertainty” (tmu) as a measure of “*fitness for intended use*” of the measurement result
- a target measurement uncertainty is decided**
- P De Bièvre 2009: MCH V SAO PAULO Nov 2010: CITAC TEL-AVIV Jan

- Impressive example of ambiguous terminology

## 1.9 measurement unit

real scalar quantity, defined and adopted by convention, with which any other quantity of the same **kind** can be compared to express the ratio of the two quantities as a number

- ...
- ...
- Note 3 Measurement units of quantities of dimension one are numbers. In some cases these measurement units ... are expressed by quotients such as millimole per mole equal to  $10^{-3}$  and microgram per kilogram equal to  $10^{-9}$ .

• ...

**the choice of a measurement unit is a decision**

Units for measurement used to take man as "reference" and were created for commerce and exchange of goods

*"Es sollen sechtzehn Mann, klein und grosz, wie sie so ungefehrlich aus der Kirchen gehen, ein jeder vor den anderen seinen Schuch stellen. Dieselbigen Lenge ist, und soll seyn, ein gerecht gemyn Messrute"* (Konventionalfestlegung).

Jacob Klögel, Staatsschreiber in Oppenheim, 1575.

Grand Duchy of Baden, end of the 18th century:

- 112 different ells
- 163 different grain masses
- 80 different weights

→ chaos, fraud → Governments, in science and commerce demanded a unified measurement system in the 18th century

*"Es ist bey uns nicht so wie in grossen Königreichen, wo die weite entfernung der provinzen alle neuen einrichtungen fast unmöglich machet: Mit geringer mühe könnte in unseren gränzen nur eine Maass, eine Elle, ein Gewicht, eingeführt werden"*.

*"Beschreibung der Gewichten und Maassen der Stadt Bern", 1770.*

source: U Feller EAM

PD/BS/9125

**The balance, used in early chemistry, compares amounts of substance by comparing mass or "weights"**

From early times, mass (or weights)  
Were compared by a single instrument:  
**the balance**

Recognising its status, science gave this  
measuring process a base (SI) unit:  
**the kg**

But science and technology discovered the  
fact that atoms combine in simple  
numbers, so chemists cannot use the  
balance directly to compare amounts of  
substance.

They must divide mass values by  
"atomic weights" to get what they need.  
The balance does not take into account  
the particulate nature of matter.

**THE (ISOTOPE) MASS SPECTROMETER (IMS) : THE MODERN CHEMISTS'S BALANCE**

What chemists need is given by the IMS!  
it directly compares

numbers of isotopic atoms:  $R_B = \frac{N(^E)}{N(^E)}$

in the international SI unit:  
the mole (a multiple of 1)

in IDMS the IMS sorts - then counts and  
compares an unknown number  $N(^E)$   
of atoms of an element

to an added known number  $N(^E)$   
of atoms of that element , through  
a ratio of numbers of isotopic atoms.

PDB93038a

$$\frac{m(A) / m(\text{kg})}{m(B) / m(\text{kg})} = \frac{m(A)}{m(B)}$$

mass values of samples of material X and Y are comparable because measured in the same unit

kg

[note that numerator and denominator being ratio-ed to the same unit, leads to a numerical value with unit one]

$$\frac{N(E,A)}{N(E,B)} = \frac{N(E,A) / N_A}{N(E,B) / N_A} = \frac{n(E,A)}{n(E,B)}$$

numbers of a specified entity, here of element E, in materials A and B, are comparable because measured in number N of specified entity (same unit one) or in same “bunch” of entities (same unit mol)

Source: P De Bièvre, Fresenius J Anal Chem 361 (1998) 227 - 234

Elements (symbol E) :

$$\frac{N(iE)}{N(jE)} = \frac{K(iE^+)}{K(jE^+)} \cdot \frac{I(jE^+)}{I(iE^+)} = K(iE^+, jE^+) \cdot r(iE^+, jE^+)$$

$$R_{i,j} = K_{i,j} \cdot r_{i,j}$$

Compounds (symbol Cp) :

$$\frac{N(iCp)}{N(jCp)} = \frac{K(iCp^+)}{K(jCp^+)} \cdot \frac{I(jCp^+)}{I(iCp^+)} = K(iCp^+, jCp^+) \cdot r(iCp^+, jCp^+)$$

$$R_{i,j} = K_{i,j} \cdot r_{i,j}$$

Isotopes (symbol <sup>i</sup>E) :

$$\frac{N(^iE)}{N(^jE)} = \frac{K(^iE^+)}{K(^jE^+)} \cdot \frac{I(^jE^+)}{I(^iE^+)} = K(^iE^+, ^jE^+) \cdot r(^iE^+, ^jE^+)$$

$$R_{i,j} = K_{i,j} \cdot r_{i,j}$$

We transform the problem of the measurement of a difficult-to-measure quantity (a number ratio) into the measurement of an easy-to-measure quantity (an electric current ratio); the conversion factor K must be measured and its measurement uncertainty evaluated.

measurements of mass use  
a property of matter called '*inertia*'  
this property is *not substance-specific*

measurements of amount use  
a property of matter called '*numerosity*'  
this property is *substance-specific*

in addition:

most of our analytical measurement procedures and  
measurement equipment, is based on the use of  
the property of matter called '*numerosity*'  
this property is *substance specific*

The choice of the property of matter (*inertia* or *numerosity*)  
which we will use as basis for our choosing the  
measurement unit for a measurement,  
is a *decision*

**All these *decisions* are to be made  
in function of the intended use of the  
measurement result**

**this intended use follows from**

- **the identification of the needs  
we decide to investigate**
- **the identification of the problems  
we set ourselves to solve**

For everybody, MiC concepts are the  
"spectacles" of the analytical chemist;

they are tools like the Hubble telescope:  
before repair, the sky looked fuzzy
